

## 1. IPv4 Addressing

a) Best-fit netmask for 25 hosts and 2 routers A network with 25 hosts and 2 routers requires 27 IP addresses. The number of usable IPs in a subnet is  $2^{\{32 - \text{prefix}\}} - 2$ . A /27 subnet provides  $2^5 - 2 = 30$  IP addresses.

- Best-fit netmask: 255.255.255.224 or /27
- Unused IP addresses:  $30 - 27 = 3$  unused addresses.

b) Division of 10.20.0.0/22 into equal-sized subnets (min 50 IPs each) Each subnet must support at least 50 usable IP addresses. The smallest subnet size that supports 50 usable IPs is a /26, which provides  $2^6 - 2 = 62$  usable addresses. The original network is a /22.

- Maximum number of subnets:  $2^{\{26 - 22\}} = 2^4 = 16$  subnets.
- Total number of usable IP addresses:  $16 \times 62 = 992$  IP addresses available for hosts and routers across all subnets.

f) IANA and RIR for 194.71.64.0/22
